1. Field of the Invention The present invention relates to an apparatus and method for accessing a disk in a storage system. 2. Description of the Related Art A storage system such as a disk array system has a large storage capacity and includes a very large number of storage devices. The storage system is comprised of three basic components: a computer host, a storage subsystem, and an interface which connects the computer host to the storage subsystem. Data stored on the disk of the storage subsystem is accessible through the interface to the computer host via a storage path. Conventionally, in disk access apparatuses in storage systems, the method whereby data that is stored on one disk is sequentially read from one head of the storage device is called a "scatter-gather" method. A scatter-gather method transfers the data from the disk to the storage subsystem without fetching data from the storage subsystem in order. As a result, the data transfer time of the disk access apparatus is reduced. However, conventional disk access apparatuses are accompanied by the drawback that since a very large number of disk drives are used in a storage system, if one head of a disk drive fails the entire disk drive is unavailable and the data is inaccessible, and consequently, the entire storage system cannot be used. A prior art technique for enhancing the reliability of disk drives is disclosed in Japanese Patent Application, Publication No. 4-33079 in which a disk is divided into a plurality of zones and each of the divided zones is provided with a plurality of heads, and a logic control circuit checks all of the heads and if a head is confirmed to have failed the logical address range or the entire zone including the head is automatically switched to the backup head. A technique for enhancing the reliability of disk drives by providing a redundant head and a technique for controlling the operation of the redundant head by a microprocessor are also disclosed in Japanese Patent Application, Publication No. 4-33079. The conventional technique for enhancing the reliability of disk drives manages the heads of all of the disk drives by using a logic control circuit. Consequently, the performance of the disk drive accessing apparatus is reduced and the data transfer time is increased. Moreover, if one of the heads of a disk drive fails the entire disk drive is unavailable and the storage system cannot be used. Furthermore, the conventional techniques for enhancing the reliability of disk drives do not address the problem that the disk drives in the storage system become unavailable due to any other failure, such as, due to a defective
